# OUR TARGET HERE

ENDEMIC SPECIES PROTECTION

## PROBLEM STATEMENT

- Preventing logging and oil companies from redeveloping vital areas like the Amazon rainforest
- Habitat loss could lead to the permanent loss of endemic species
- Difficulty in proving and cataloguing the existence of these species
- Central focus: Cataloging endemic species

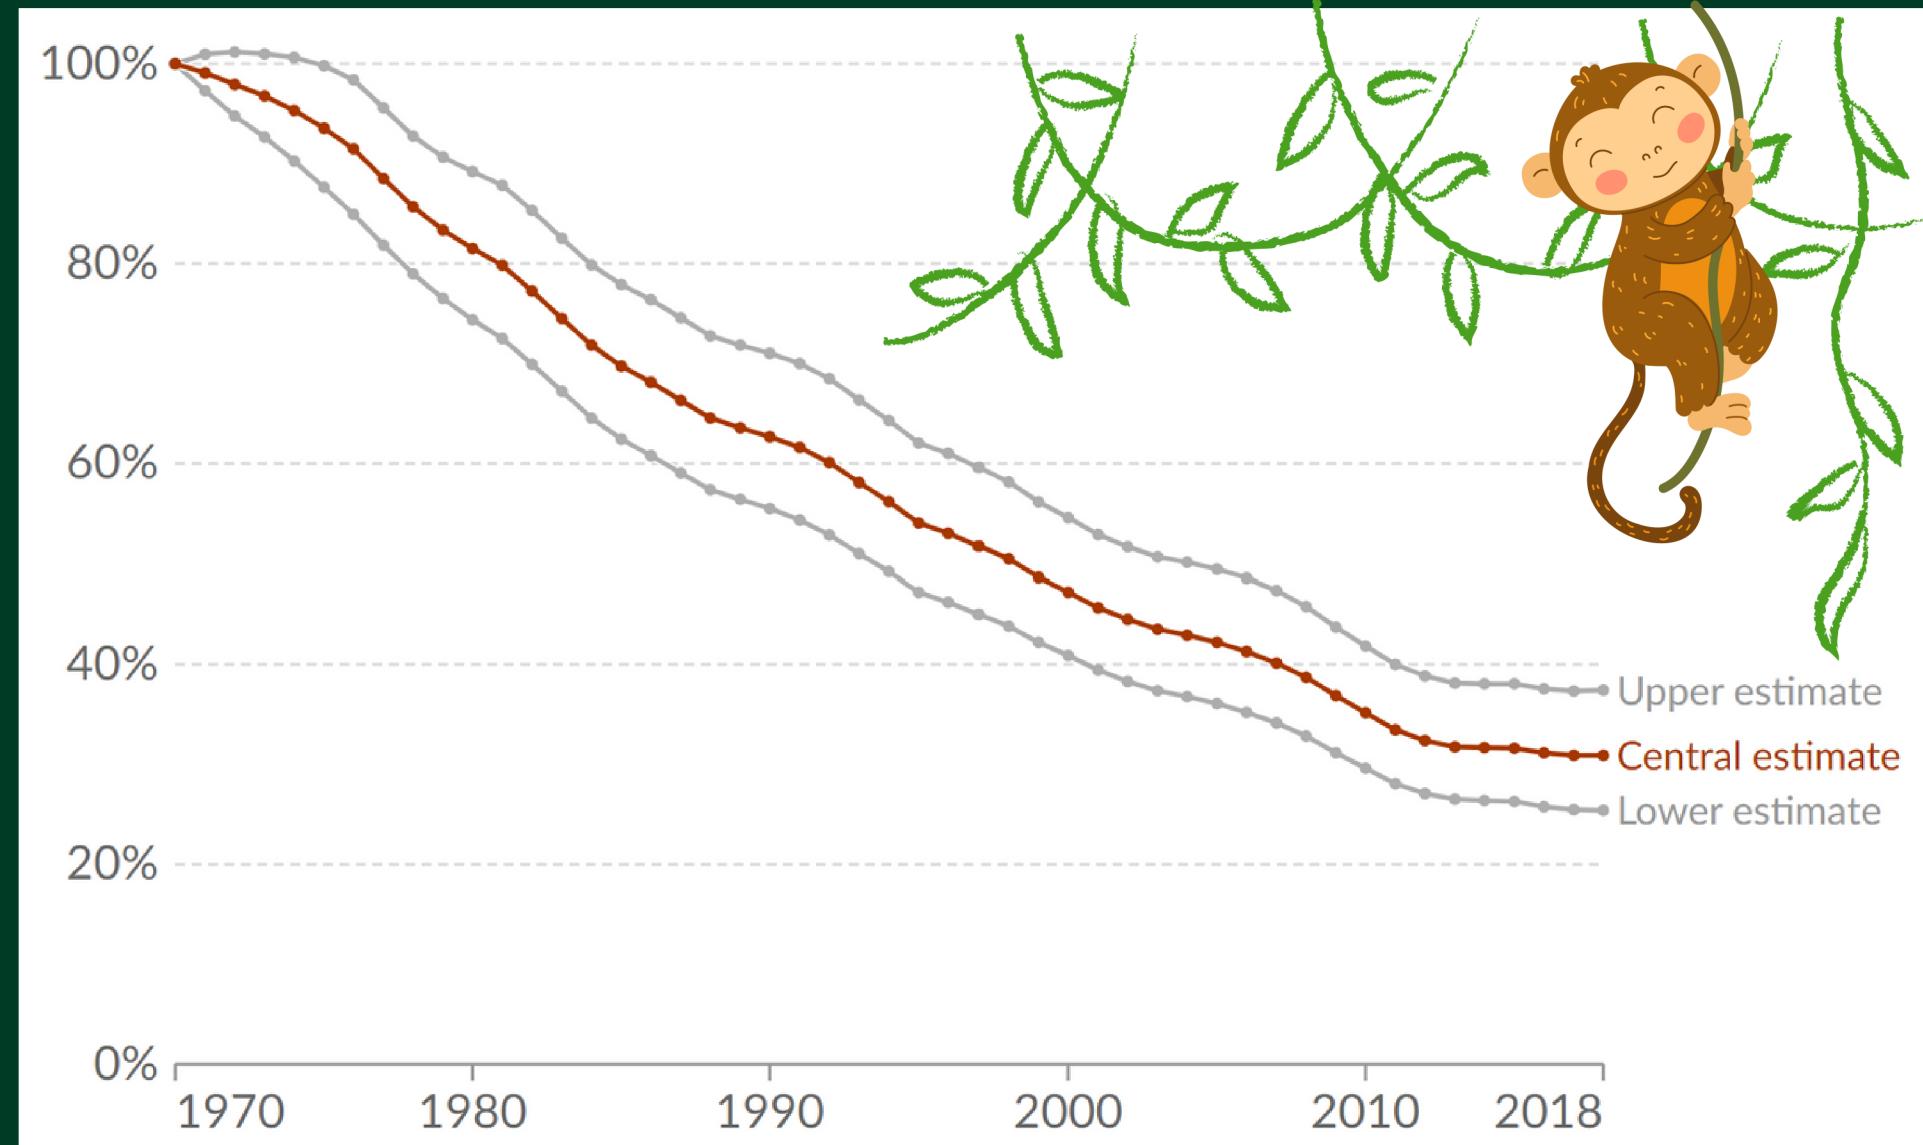

Fig.: Average decline in wildlife populations over the years

Wildlife Statistics: <https://ourworldindata.org/biodiversity>

## SEE SHOCKING FACTS!

- Approximately 30,000 species per year (about three per hour) are being driven to extinction
  - Harvard University
- Approximately 80% of the decline in global biological diversity is caused by habitat destruction.
  - African Conservancy
- Global wildlife populations have plummeted by 69% on average since 1970.
  - WWF

# OUR VISION

## Proposed Solution:

- Train an animal image recognition network to be able to quickly prove whether an animal only photographed a few times is in fact a new species or not.
- Fine-tune the network with a triplet loss function to act as a Siamese face recognition type network.
- Quickly add new species to the database as new species are discovered.
- Lead to cataloguing and differentiating between hundreds of species as they are being discovered.

# TARGET AUDIENCE

- Governmental and nongovernmental organizations concerned about wildlife conservation.
- They can use the proposed solution to differentiate between different known and newly discovered species and take the right actions to protect them.

# UNIQUENESS

## Vision 1

Better at differentiating different classes than a classifier because it uses the triplet loss function

## Vision 2

You can add new species to the database with a handful of photos and no extra training

## Vision 3

The network can be run on a mobile phone without an internet connection

# METHODOLOGY

- 01.** Sample images from 25 animal classes in the CIFAR100 dataset
- 02.** Convert classifier network pretrained on ImageNet1K to a recognition network using triplet loss
- 03.** Fine-tune recognition network on CIFAR100 animal data

# 1. DATASET COLLECTION AND PREPROCESSING

**Custom Datasets and Data Loaders in PyTorch for training, validation, and testing.**

- We created TrainingDataset for training data and a ValidationDataset for validation data
- The TestingDataset combines pre-trained data and new images for testing.
- The data loaders efficiently handle data batches for neural network training and evaluation.

## 2. PRETRAINED IMAGENET1K CLASSIFIER TO TRIPLET LOSS

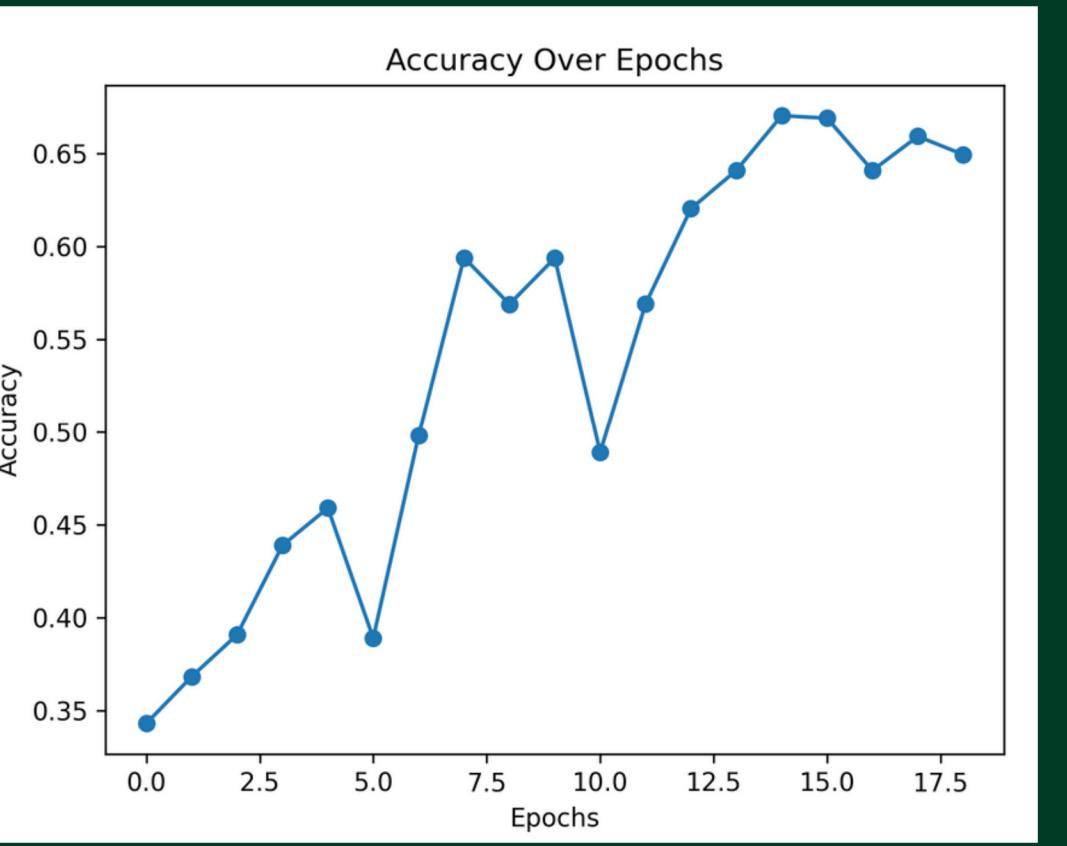

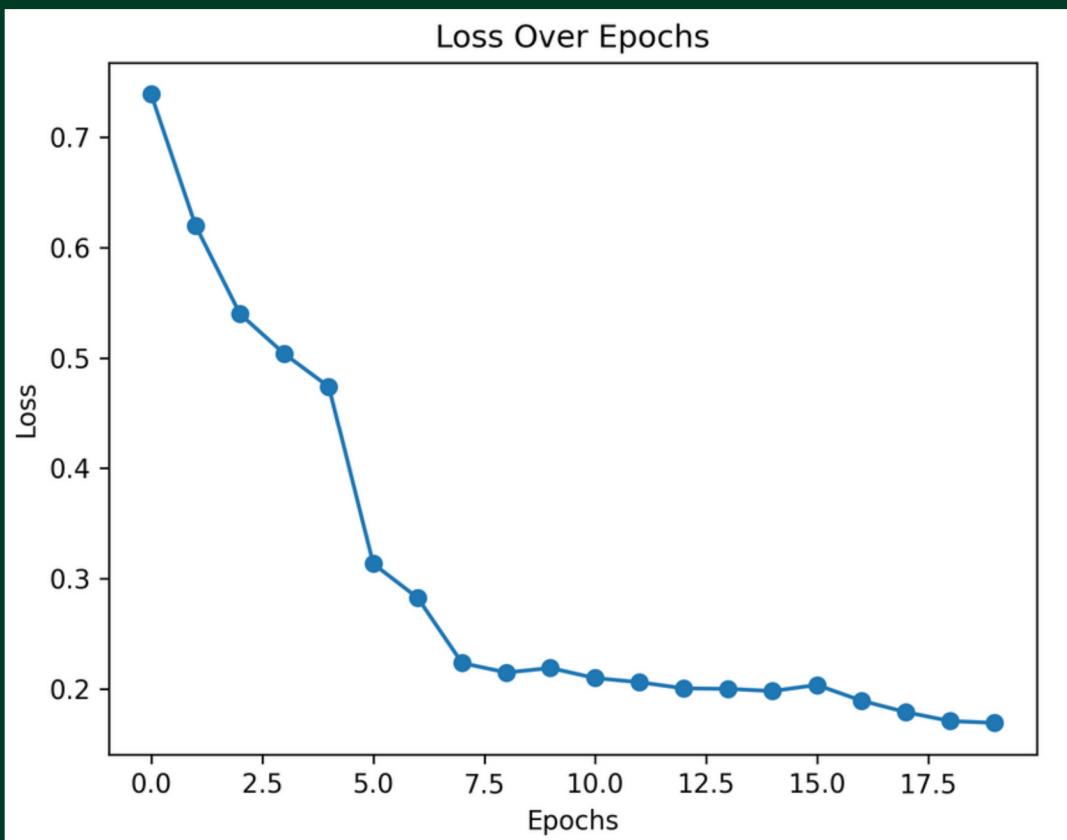

```
15 model = mobilenet_v3_small(weights='IMAGENET1K_V1')
16
17 for name, param in model.named_parameters():
18     if 'classifier' not in name:
19         param.requires_grad = False
20
21 model.classifier[-1].out_features = 128
22
23 loss_function = torch.nn.TripletMarginLoss()
```

# 3. FINE-TUNING RECOGNITION NETWORK ON CIFAR100 ANIMAL DATA

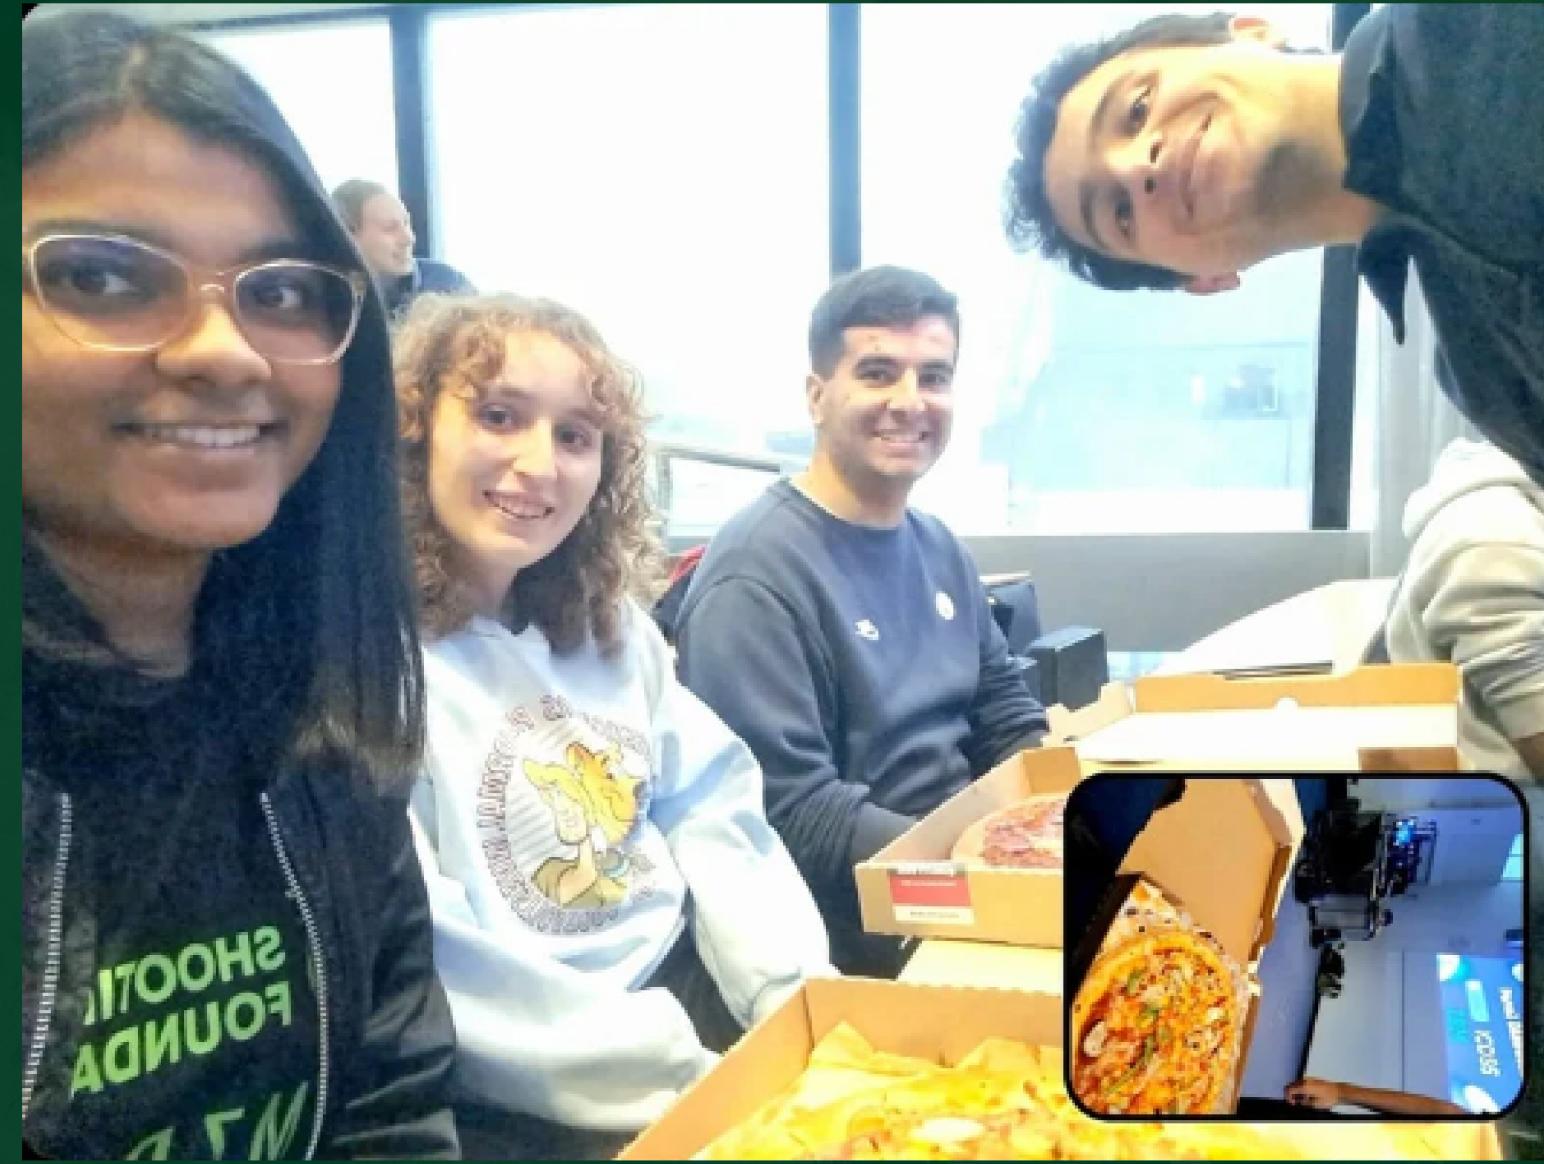

The screenshot shows a Jupyter Notebook interface with a dark theme. The top menu bar includes File, Edit, View, Run, Kernel, Tabs, Settings, and Help. The left sidebar features a file tree with a root folder named "/ ARNET /" containing subfolders Data, LICENSE, main.py, README.md, and test.py. The main area displays the content of the main.py file:

```
23 def train_one_epoch():
24     running_loss = 0.
25     for i, data in enumerate(training_dataloader):
26         anchor, positive, negative = data
27         optimizer.zero_grad()
28         anchor_output = model(anchor)
29         positive_output = model(positive)
30         negative_output = model(negative)
31         loss = loss_function(anchor_output, positive_output, negative_output)
32         loss.backward()
33         optimizer.step()
```
